TITLE: Effect of some oxides on the reduction of lead glasses

PERIODICAL: Steklo i keramika, no.12, 1962, 8 - 10

TEXT: Three problems gave rise to the present paper: (a) Semiconducting layers forming on glass surfaces by reduction; (b) the problem of eliminating the discoloration of glasses on thermal treatment in a reducing atmosphere; (c) effect of the chemical structure of glasses on the diffusion of reducing gases. Binary P-40 (R-40) lead glasses consisting of 60% SiO_2 and 40% PbO were used. At a constant content of PbO , 5 or 10% SiO_2 was replaced by Na_2O , BaO , ZnO , CdO , B_2O_3 , Al_2O_3 , TiO_2 , V_2O_6 , Cr_2O_3 , MnO_2 , Fe_2O_3 , CoO , or NiO at $1250 - 1300^\circ\text{C}$ (30 - 40 min), then the glass was reduced for 4 hrs in a hydrogen atmosphere at 400°C . The transparency T_λ was measured spectrophotometrically in the $350 - 1100 \mu\text{m}$

✓

Card 1/3

S/072/62/000/012/001/001

Effect of some oxides on the reduction ... B101/B144

region. The integral transparency S was determined from the curve T_λ versus λ and the change was calculated to be $T_{\text{red}} = \sqrt{S_1/S_0}$, where S_1 is the integral transparency of reduced, and S_0 of non-reduced glasses.

Furthermore, glasses in which Li_2O , Na_2O , K_2O , Rb_2O , or Cs_2O , were substituted for 15% SiO_2 , were reduced for 3 hrs in H_2 at 360°C , and the transparency was also measured. Results: Glasses containing 5 and 10% Cr_2O_3 and 10% NiO crystallized; the transparency of specimens containing 10% CoO was too low. The other specimens showed the possibility of classifying oxides under the experimental conditions: (1) Oxides that support the Pb reduction: V_2O_5 , NiO , Al_2O_3 , and to a smaller extent also Na_2O ; (2) oxides by which the reduction is not affected: TiO_2 , CoO , B_2O_3 , and CdO ; (3) oxides inhibiting the reduction of Pb: $\text{Fe}_2\text{O}_3 > \text{MnO}_2 > \text{ZnO} > \text{BaO}$.

Hence it is concluded that new electrochemical glasses, very stable to thermal treatment in a reducing atmosphere, can be produced from lead glasses containing Fe_2O_3 or MnO_2 . The increase in reducibility of lead

glass with the radius of the alkali ion is explained by the glass structure being loosened as the alkali ion radius increases, which favors the diffusion of hydrogen and polarization of oxygen, thus reducing Si-O-Si bond is reduced. TOPIC TAGS: glass, crystallization, precrystallization period, crystallization catalyst, cordierite, electron microscopy, thermography

ABSTRACT: The temperature conditions during the so-called precrystallization period demonstrated experimentally in the catalyzed crystallization of glass, exert a great effect on the subsequent crystallization process and hence on the structure and properties of the final product glass ceramics. In order to study the processes in the production of glass ceramics, a glass composition based on cordierite was chosen in the $\text{SiO}_2\text{-Al}_2\text{O}_3\text{-MgO}$ system. The catalysts used were oxides of the elements of group IV of the periodic table (TiO_2 , SnO_2ZrO_2 , PbO) as well as fluorine. Complex experimental methods, such as

Cord 1/2

ACCESSION NR: AT4019279

x-ray, differential thermography and electron microscopy were used. A relationship is established between the properties, structure, and phase composition of the material and the conditions of thermal treatment of glass. Differential thermal analysis of glass showed that the formation of the first crystalline phase occurs at 815C. Any temperature below this is a precrystallization period. A relationship is also established between the temperature of the maximum exothermic effect, connected with the formation of mullite, and the temperature of the thermal treatment of glass in the precrystallization stage. The dependence of the density γ , the thermal expansion coefficient α and the strength R on the crystallization temperature is plotted at different times of precrystallization. Structural changes, depending on the temperature of precrystallization are illustrated by micro-photographs. From the investigations, general rules are established which are typical for heterogeneous crystallization and independent of the composition of the initial glass. This makes it possible to control the crystallization of glass to a greater extent by choosing the optimal conditions of thermal treatment. Orig. art. has: 10 figures.

TOPIC TAGS: glass, glassy-crystalline material, eucryptite, spodumene, petalite, x-ray diffraction, lithium aluminosilicate

ABSTRACT: Roentgenographic studies were carried out to follow the changes in the phase composition of glassy-crystalline materials of the systems $\text{Li}_2\text{O}-\text{Al}_2\text{O}_3-\text{SiO}_2$ and $\text{Li}_2\text{O}-\text{MgO}-\text{Al}_2\text{O}_3-\text{SiO}_2$ with different molecular ratios of the oxides during thermal treatment. The ternary system includes three minerals found in nature: eucryptite (molecular ratio of oxides 1:1:2), spodumene (1:1:4) and petalite (1:1:8). It is suggested that the structuralCard
1/2

ACCESSION NR: AT4019303

changes observed are connected with one of the following phenomena: The formation of a "second phase" (the composition of which cannot be determined by the x-ray data obtained for compounds of this system) or the modified transformation of β -spodumene from the low-temperature form, stable in a temperature range of 700-800C to a high-temperature form, stable at temperatures higher than 900C. The formation of a second phase was observed in all cases with oxide ratios between 1:1:4 and 1:1:10. If the line of the "second phase" was eliminated, the x-ray diagrams of the compounds with oxide ratios from 1:1:2 to 1:1:10 were very similar and differed only by a shift of the lines toward greater values of Θ during the transition from the compound 1:1:2 to the compound 1:1:10. This effect is probably connected with the formation of a wide range of solid solutions, including β -eucryptite, β -spodumene and petalite. However, both hypotheses can be verified only by the preparation of monocrystals of β -spodumene. Orig. art. has: 3 figures.

TOPIC TAGS: glass, glassy-crystalline material, glass structure, electron microscopy, calcium fluoride, sodium fluosilicate, slag

ABSTRACT: Glasses obtained from metallurgic slags were investigated with the TESLA BS 242A electron microscope at a voltage of 60 kv and a magnification of about 6000 X. The cleavage plane and the conditions of investigation are described. Slag ceramics with a fine-grain structure and a crystal length ranging from 0.1 to 2 microns were test samples. The electron photomicrographs of the fracture plane of slag glassy-crystalline materials obtained with different additives by the same thermal treatment (950C, 3 hours) are shown. It was found that
Card 172

ACCESSION NR: AT4019314

the addition of 25% Na_2SiF_6 leads to the formation of a microcrystalline structure and that the principal crystalline phases are calcium fluoride (CaF_2) and anorthite ($\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot2\text{SiO}_2$). A decrease in the amount of sodium fluosilicate led to an increase in the size of the anorthite lamellae to a length of 2 μ . With the addition of TiO_2 the crystals became rod-shaped and drop-shaped. Roentgenographic analysis of this crystalline phase showed titanite ($\text{CaO}\cdot\text{TiO}_2\cdot\text{SiO}_2$). The slag ceramic material with the best mechanical properties was characterized by a densely packed microcrystalline structure with a particle size of 0.1-0.3 μ . Orig. art. has: 4 figures.

TITLE: Strengthening of plate glass by etching

PERIODICAL: Steklo i keramika, no. 4, 1963, 4 -8

TEXT: A study was made of the etching-law sequence of glass under tension or non-tension. The possibilities of evaluating the microdefects according to magnitude and shape were analyzed. The causes of defect occurrence and the prevention of new damage to the etched glass were investigated. A 2 - 3 mm plate glass (72 SiO₂, 15 Na₂O, 8 CaO, 3.5 MgO and 1.5 Al₂O₃) with vertical stretch was used for the analysis. The bending strength was calculated from the formula: $\sigma = 4.45 P/h^2$, where P is the destructive load in kg, h - the sample thickness in mm. The centro-symmetrical strength was determined from the formula: $\sigma = 0.824 P/h^2$. A linear relation was derived between glass strength and etching time or thickness of the removed layer. A comparison of the obtained relation with the theoretical Griffith formula is made: $\sigma = \sqrt{\frac{2ET}{h}}$, where E is the resili-

ence modulus, equaling $7,000 \text{ kg/mm}^2$, T - the surface energy $5 \cdot 10^{-5} \text{ kg/mm}$, c - crack size, equalized to the thickness of the defective layer in mm. Thus, an indirect evaluation of magnitude and shape of the surface microdefects can be made. The method of gradual etching helps to judge not only the change in the defects during the strengthening process, but also of the differences in their initial shape. It is pointed out that the removal of the damaged surface layer does not protect the glass against further damage from either mechanical, corrosive or thermal causes. It was established that the action of moisture or heating to a temperature of calcination has much less effect on the reduction in strength of the etched glass than the mechanical damage of its surface. It is further shown that the application of a fine layer of material on its surface, with the ability to reduce the surface friction coefficient, can be used as a method of etched-glass protection from mechanical damage. There are 4 figures and 1 table.

SYNTHESIS OF SITALLS FROM SLAGS (USSR)

Kitaygorodskiy, I. I. IN: Vsesoyuznoye khimicheskoye obshchestvo,
Zhurnal, v. 8 no. 2, 1963, 192-197. S/063/63/008/002/011/015

Studies which led to the development of the glass-bonded ceramic materials Pyroceram in the USA and sitalls in the USSR by the Moscow "Order of Lenin" Institute of Chemical Technology imeni D. I. Mendeleyev (MKhTI) are briefly reviewed. It is stated that, in contrast to pyroceram, sitalls based on the cordierite system are produced by a simple process which involves catalytic polymerization [the catalyst is not specified in the article] of cheap materials without irradiation by short-wave rays. The Soviet process takes into account the results of preliminary studies which showed that heat treatment of glass in the precrystallization period (microliquation and formation of crystallization nuclei) causes considerable changes in the structure of the glass, indicated by changes in the properties of the glass, and strongly affects subsequent crystallization of the glass. Prolonged heat treatment in the vicinity of T_g causes a gradual "ordering" of the glass structure with the formation of regions whose structure approaches that of the crystalline

Card 1/2

SYNTHESIS OF SITALLS FROM SLAGS [Cont'd]

S/063/63/008/002/011/015

phase. This process is slow and results in the transition of glass into sitalls. Study of the precrystallization process casts doubt on the existence of a unique glassy state and indicates that this state must be considered metastable and intermediate between the liquid and solid states. The "sitallization" conditions of glass can vary within broad limits, depending on the composition of the initial glasses and the required properties of the sitalls. The problem of finding cheap raw materials for sitalls was solved by the use of liquid and solidified metallurgical slags. After studying the solidification of glass and the significance of its solidification rate, MKhTI formulated the theoretical principles of the conversion of molten slags into glass and developed a process for producing sitalls by controlled crystallization of slag glass. The sitalls produced have a very fine, uniform structure. They are extremely long-lasting and can be used as construction materials, substitutes for ferrous metals, and insulating and reinforced foamed materials. Slag glass can be used for the production of containers and glass-fiber materials. "Sitallurgy" is a promising industry because 1) its raw material sources in the form of slags are unlimited; 2) it utilizes the thermal energy of waste slags; and 3) it permits the use of existing equipment in the glass industry.

TITLE: Electric properties of alumo-boro-silicate glasses

SOURCE: Steklo i keramika, no. 6, 1964, 5-8

TOPIC TAGS: alumo boro silicate glass, glass electro resistivity,
glass dielectric constant, glass dielectric loss, electric property

ABSTRACT: The work was prompted by the scarcity of data concerning the electric properties of alumo-boro-silicate glasses, despite the fact that they attract growing interest because of their high electro insulating properties. The authors investigated glasses of the following compositions (wt%) 62.4 SiO₂, 8 B₂O₃, 8 Al₂O₃, 20 RO, 1.6 K₂O and 64 SiO₂, 8 B₂O₃, 8 Al₂O₃, 20 RO, where R = MgO, CaO, SrO, BaO and PbO. The influence of chemical composition, field frequency and temperature on electric properties: (dielectric constant, resistivity and dielectric losses) was investigated, for all glass types electric resistivity ρ expressed as $\log \rho - 1/T$ is linear (T= temp). Cation mobility determines the electroconductivity of glass (the Pb cation being an exception because of lead glass

Card 1/2

ACCESSION NR: AP4040681

lower viscosity at high temperatures). Dielectric losses, $\tan \delta$, were studied in the range from 10⁵ to 3·10⁹ cycles. It was found that losses are at their lowest point at medium frequencies: 10⁶ - 10⁷ cycles. The losses of lead glass are similar to those of barium glass. An increase of the loss angle is observed at temperatures rising from 20 to 300°C. Dielectric constant & of low alkalinity glasses increases with the introduction of one divalent oxide instead of another - in proportion to the increasing radius of the cation. With increasing field frequency, dielectric constant rapidly decreases when frequency exceeds 10⁷. It increases with temperature due to shorter relaxation time. Orig. art. has: 5 figures.

ACCESSION NR: AR5007236

The results showed that it is possible to strengthen various glasses, differing
in composition and properties, quite appreciably by quenching them in liquid
nitrogen. It was found that the effects of the thermal conditions of the quenching
process on the regularities of the chemical composition of the glass on the
strength of the glass. The regularities of the strengthening are elucidated. Along with 12

ABSTRACT: Electron microscope analysis and x-ray diffraction is investigating crystalline glass surfaces.

CITATION: USSR. Doklady*, v. 154, no. 4, p. 851, 1964.

TOPIC: X-ray analysis, electron microscope analysis, x-ray diffraction, glass, glass surface, crystallization kinetics

ABSTRACT: The joint use of electron microscope analysis and x-ray analysis gives valuable information about the structure of new glass materials, permits the study of crystallization kinetics following the formation of a certain number of crystals, and helps to identify the crystals on the microspectrophotograph and determine the function of the crystal size, temperature and composition of the glass melt. The authors also report on the use of electron microscope analysis to study the structure of glass surfaces.

TITLE: Phase changes in the process of catalytic crystallization of glass in the $\text{SiO}_2\text{-Al}_2\text{O}_3\text{-MgO}$ system

SOURCE: AN SSSR. Doklady*, v. 155, no. 2, 1964, 370-373

TOPIC TAGS: glass crystallization, cordierite, titanium dioxide catalyst, solid solution, high temperature quartz, quartz, spinel, sapphirine, x ray analysis, thermal analysis, cordierite

ABSTRACT: The crystallization process in glass having the cordierite composition, and in such glass containing 10 mol.% TiO_2 as the catalytic additive, was investigated. The crystallization of the following phases was observed: at about 850°C--a solid solution based on high temperature quartz; 900-1000°C-quartz; 900-950°C--spinel; 1000-1100°C--sapphirine; 1200°C--cordierite. From

Card 1/5

ACCESSION NR: AP4022718

x-ray analysis it was determined that cordierite is not formed directly from glass, but through the following series of intermediate compounds: (1) separation of the first crystallization phase, solid solutions of type O silica; (2) breakdown of the solid solution with the formation of quartz, spinel and rutile; (3) conversion of the spinel to sapphirine; (4) interaction of sapphirine with quartz to form cordierite (fig. 1). Thermal analysis confirmed exothermic effects (fig. 2). The addition of TiO₂ did not cause separation of a low temperature form of cordierite-- μ -cordierite, as was reported by M.D. Karkhanavala and F.A. Hummel (J. Am. Ceram. Soc., 36, 12 (1953)). Using the Karkhanavala method of synthesis, μ -cordierite was formed only after heating for 150 hours. It is concluded that μ -cordierite is not a compound with constant composition, but one of the members of the solid solution based on high temperature quartz. Orig. art. has: 1 table and 2 figures.

TITLE: Strengthening of glass by hardening in molten metal

SOURCE: AN SSSR. Doklady, v. 158, no. 3, 1964, 582-585

TOPIC TAGS: glass heat treatment, glass hardening, molten metal treatment, glass strengthening, sheet glass, Pyrex glass

ABSTRACT: A new, more efficient method of strengthening glasses having varied thermal expansion coefficients has been developed and investigated. The method consists in heat treating (hardening) glass in low-melting molten metals such as wood alloy or tin and then leaching it with hydrofluoric acid. Data from bending tests indicated that glasses with high or low coefficients of thermal expansion (common sheet glass and 3C-SK or Pyrex, respectively) can be greatly strengthened by the new method. An especially high increase in strength was achieved in thin (1.3-mm) sheet glass and in the heat-resistant glasses, as compared to the heat treatment with the most

Card 1/2

L 13964-65

ACCESSION NR: AP4046372

efficient liquid polyorganosiloxane. Data on comparative degrees of hardening for Pyrex glass indicated a much higher strengthening effect for the treatment with wood alloy than with the liquid polyorganosiloxane. This fact is explained by the intense and uniform cooling of glass in molten metal. Such cooling is achieved because of the high thermal conductivity and very high boiling point of the metals, which make possible a high-temperature (50—1000°C) treatment resulting in limitation of thermoelastic strain in glass products. The possibility of achieving even higher strength in glasses having important practical applications (Pyrex, common thin glass) is mentioned. Orig. art. has: 3 figures and 1 table.

Received: May 1, 1969. Reorganizational material, p. 1, dated 1969.

Abstract: glass crystallization, phosphorus pentoxide, alkali glass, glass and melt phase separation, electron microscopy, glass opacity.

Two samples of glass having the following composition were prepared: 72.7% Na₂O, 14.7% P₂O₅, 10.6% SiO₂. The samples of P₂O₅ were added to the glass melt in two different heat treatments. The first treatment was a slow heating rate followed by a rapid cooling rate. The second treatment was a rapid heating rate followed by a slow cooling rate.

The results of the heat treatment will be shown. The electron micrographs show the effect of the heat treatment on the glass opacity.

Effect of molten slag in the process of float glass

production - protective - no grain breaking solution

glass, float glass, slag glass, aluminosilicate glass, float glass, PTFE
coated float glass, float glass

The effect of the changes in pressure, temperature, and time, as
well as mechanical stirring of the molten slag, on the formation
of glass has been discussed and experiments made to determine
the mechanism of production of glass. These results have been
obtained by using either a float or a PTFE coated float
method of glass production. The results show that the
formation of glass depends on the following factors:
These may be summarized as:

2025 RELEASE UNDER E.O. 14176

SP-1000-A-1000-029

AUTHOR: Kitaygorodskiy, L. I.; Petrov, S. V.; Yegorova, I. S.

TITLE: Effect of heat treatment on the phase composition of slag pyroceramics

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 1, no. 6, 1965, 936-942

TOPIC TAGS: pyroceramic, slag, calcium silicate, glass crystallization

ABSTRACT: In order to prepare slag pyroceramics, a study of the effect of heat treatment conditions on the phase composition and strength characteristics of glass-crystalline materials was carried out. The glasses investigated were prepared from synthetic compositions in the system $\text{CaO} - \text{Al}_2\text{O}_3 - \text{SiO}_2$ and subjected to one-, two-, and three-stage heat treatments. X-ray analysis was used to determine the crystalline phases. The heat treatment was found to determine the nature of the crystalline phases and their content. The crystallization of glasses based on the compositions forms various calcium silicates (pseudowollastonite $\text{Ca}_2\text{Si}_2\text{O}_7$ and wollastonite CaSiO_3) as the crystalline phases. Such phases in the glass-crystalline materials based on the slags are pseudowollastonite and anorthite $\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$. A relative increase in the

Card 1/2

L 60952-65

ACCESSION NR: AP5018929

degree of crystallization of the material is usually associated with an increase in strength; the maximum strength corresponded to conditions of treatment where the habit and physical properties of the crystalline phase formed differed from those of the phases already present. Orig. art. has: 6 figures and 1 table.

1. Effect of the composition of neodymium-activated A₂BBF on the absorption

2. spectra and the luminescence lifetime

SOURCE: AN SSSR. Doklady, v. 161, no. 1, 1965, 118-121

1. SiO₂ silicate glass, germanate glass, neodymium activated glass, laser sys-

2. tem, light absorption spectrum, luminescence lifetime, glass composition

ABSTRACT. In connection with the problem of devising more powerful laser systems, the light absorption and luminescence of neodymium-activated alkali silicate and germanate glasses have been studied. The interest in activation by the Nd³⁺ ion was prompted by the reported relative facility of population inversion with Nd, without cooling to a low temperature. The purpose of the study was to determine the effect of glass-forming oxides (Si, Al, B, Ti, etc.) and of Na₂O or K₂O and the Nd³⁺ concentration in the Na₂O—Al₂O₃—B₂O₃ system on the glass properties. Absorption spectra were plotted, maximum sizes and positions of the absorption bands and luminescence lifetimes were measured at room temperature for samples with ratios in the 1:1 to 1:11 range and for 1:1, 1:4, 1:10 in the glass systems studied. The glasses were prepared by melting chemically pure materials at 1200 to

Card 1

L 37698-65

ACCESSION NR: AP9009224

1500C. Luminescence was excited with an IFK-2000 lamp. In the silicate systems, at a constant Nd_2O_3 content (2% by weight), the width of absorption bands and E maxima increased with an increase in alkali content. Simultaneously, i increased to a maximum, then started to decrease. The maximum i was 800 usec for the $\text{K}_2\text{O}:\text{K}_2\text{O} = 1:7$, much lower for the same ratio in the $\text{Na}_2\text{O}-\text{SiO}_2$ system, and 560 usec for the $\text{CaO}_2:\text{K}_2\text{O} = 1:3$. In the $\text{K}_2\text{O}-\text{GeO}_2$ system, the fine structure of absorption spectrum and E maximum for 573 m μ were observed at the same i ratio. The width of the absorption bands in $\text{K}_2\text{O}-\text{GeO}_2$ system varied in the direction opposite to that in the $\text{K}_2\text{O}-\text{SiO}_2$ system, i.e., decreased when the K_2O content was increased. The finest absorption structure was observed in the $\text{K}_2\text{O}-\text{SiO}_2$ system. As expected, increased with an increase in the Nd_2O_3 concentration in the $(\text{K}_2\text{O})_2\text{SiO}_4$ and $\text{K}_2\text{O}-\text{Na}_2\text{O}$ glasses, because of concentration quenching of luminescence. The above facts were discussed on the basis of coordination between ions in glass structures and the interaction of Nd^{3+} with surrounding oxygen ions. In rutileum glasses, i was found to be significantly high than in potassium glasses. Original art has 3 figures and 1 table.

TITLE: Effect of the nature of crystallization of glass on the structure of foam glass

SOURCE: AN SSSR. Doklady, v. 162, no. 6, 1965, 1339-1341, and insert facing p. 1340

TOPIC TAGS: foam glass, glass crystallization, glass structure

ABSTRACT: The authors studied the preparation of foam glass from alkali-free and low-alkali boron-free glasses differing both in composition and in crystallizing properties. An investigation of the foamability of the glasses showed that a high degree of crystallization sometimes has a negative effect on the foaming and structure of foam glass (glasses Nos. 13v, 2, 3, 4, and 5), and even prevents its formation (glass No. 87). In other cases, foam glass with regular, fine closed pores is obtained (No. 61) from glass which crystallizes to a high degree in the bulk as well as from glasses of low crystallizability such as M-519 and M-519a. To elucidate the causes of this diverse behavior, x-ray diffraction and

Cord 1/2

L 65627-65

ACCESSION NR: AP5017210

electron microscopic analyses were carried out on glasses crystallized under various conditions and on samples of foam glass. It was found that the nature of the crystallization has a pronounced effect on the structure of the foam glass obtained. The formation of a uniform, finely crystalline microstructure does not prevent the formation of a foam glass having regular, fine closed pores. Relatively coarse, nonuniform crystals impair the foamability and sometimes prevent the formation of foam glass. "The electron micrographs were taken by N. M. Vaysfel'd." Orig. art. has: 4 figures.

TITLE: Effect of phase composition and structure of slag-microcrystalline glasses (Pyrocerams) on some of their physico-chemical properties

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 2, no. 2, 1966, 376-379

TOPIC TAGS: glass property, phase composition, crystal structure

ABSTRACT: In most cases, slag Pyrocerams are polycrystalline materials in which the role of the cementing layer is played by the glass phase. However, with an increase in the amount of the glass phase, the strength of the material decreases. In addition, the bending strength is a function of the heat treatment conditions (for example, for one of these materials the average measured strength varied from 1000 to 1900 kg/cm²). Study of only one parameter of these materials, for example the character of the change in density, cannot fully explain the structural changes taking place during crystallization of the glass. The article presents a table listing the properties of several of the slag Pyrocerams. A

TITLE: Mechanism of pyroceramic conversion of glass in the liquation region of the CaO-MgO-SiO₂+(R₂O; R₂O₃) system

SOURCE: AN BSSR. Vestsi. Seryya khimichnykh nauk, no. 2, 1965, 41-45

TOPIC TAGS: silicate glass, ceramic material, pyroceramic, fluoride, liquation, thermal analysis

ABSTRACT: The authors study the process of pyroceramic conversion of glass in the ternary CaO-MgO-SiO₂ system with various concentrations of fluoride added in the form of NaF in various amounts above 100 wt.% during founding for 4 hours at a maximum temperature of 1480°C. Electron photomicrographs of this glass show a large number of nonhomogeneities with dimensions of 0.1 μ indicating active liquation of the glass. As the glass is heated to 600-700°C, these nonhomogeneities gradually increase in size reaching dimensions of 1 μ and greater. X-ray phase analysis shows no crystalline phase. These data are confirmed by differential thermal analysis. The process by which fluorine is integrated into the silicate lattice during melting of the charge is discussed as well as the separation of fluorine during cooling. Liquation in this case should apparently be considered an independent phase process instead of merely a

TITLE: Mechanism responsible for conversion of glass to pyroceramic in members of the isomorphic series of the CaO-MgO-SiO₂+(R₂O; R₂O₃) system

SOURCE: AN BSSR. Vestsi. Seryya khimichnykh navuk, no. 2, 1965, 46-51

TOPIC TAGS: silicate glass, solid solution, calcium compound, magnesium compound, ceramic material, pyroceramic

ABSTRACT: A method is proposed for using plentiful minerals as raw materials for production of economic pyroceramics with a pyroxene composition and excellent physical, mechanical, thermal and anticorrosion properties. The phase diagram of the CaO-MgO-SiO₂ system is used as a base with addition (above 100 wt.%) of R₂O and R₂O₃ in the form of Na₂O, Al₂O₃ and Fe₂O₃. This ternary system has a pyroxene field containing a continuous series of diopside-enstatite solid solutions. There is a good basis for assuming that a continuous isomorphic series passes through the entire system. This is important from the standpoint of synthesizing pyroceramics based on multicomponent raw materials (e. g. clay) since all components appearing in the original raw material

Card 1/2

L 40339-66

ACC NR: AP6007523

enter the crystalline structure of the pyroxene solid solution during conversion of the glass to pyroceramic in the isomorphous series. The glass was founded in 1-liter quartz crucibles in a gas furnace at a maximum temperature of 1450-1470°C. The optimum compositions were founded in 25-kg crucibles. The experimental specimens were subjected to gradient crystallization and heat treatment under various conditions (2, 4 and 6 hours at 600-1000°C). The pyroceramic products are subjected to comprehensive x-ray, electron microscope, petrographic and extraction analysis. The results show that pyroceramic conversion of pyroxene glass synthesized from nonmetallic raw materials is a continuously variable process. Continuous interaction between the structural complexes in the glass during heat treatment results in a pyroxene phase of variable composition. Thermograms of the glass are given. Orig. art. has: 3 figures.

TITLE: Possibility of applying the method of quantitative x-ray phase analysis to vitreous-crystalline materials

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 2, no. 4, 1966, 726-737

TOPIC TAGS: phase analysis, x-ray diffraction analysis, quartz, glass

ABSTRACT: The object of the study was to work out a technique for quantitatively determining the composition of crystalline phases in pyroceramic materials. Because of its simplicity, rapidity, and popularity, the method of quantitative x-ray phase analysis was chosen. Two variants of this method were used: (1) direct measurement of the intensity of diffraction reflection (plotting of calibration graph in the coordinates I vs. % of crystalline phase), (2) internal standard (plotting of calibration graph in the coordinates I/I_{st} vs. % of crystalline phase). A quantitative x-ray phase analysis was carried out on pyroceramic material of the $\text{SiO}_2\text{-Al}_2\text{O}_3\text{-MgO}$ system containing three crystalline phases: quartz, spinel, and rutile, and both variants were shown to yield satisfactory results. Because of the characteristics of the pyroceramic structure, more accurate data on the content of crystalline phases are provided by measurements of the integral intensity (area under the peak). The results of the x-ray phase analysis

Title : Piezoelectric materials made of pressed barium titanate

Periodical : Zhur. tekhn. fiz., 24, 1371-1374, Aug 1954

Abstract : Obtained barium meta-titanate and solid solutions of barium and lead meta-titanate by firing at temperatures up to 1250°C and by successive pressing with organic binders. Found that these samples possess piezoelectric properties after polarization, but that pressed solid solutions of barium and lead meta-titanate possess greater piezoelectric moduli than the barium meta-titanate samples, which is explained by the lower caking temperatures of the solid solution. TITLE: On the coefficient of vertical turbulent exchange in the sea. (O koefitsiente vertikal'nogo turbulentnogo obmena v more).

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya, 1957, No.9, pp.1118-1132 (USSR)

ABSTRACT: The fundamental results are considered of applying the "semi-empirical theory of turbulence" to the analysis of the dynamic processes in the sea. A simplified method is used for calculating the coefficient of turbulent viscosity caused by the simultaneous action of wind driven waves and currents. A comparative evaluation is given of the role of wind driven waves and currents in the development of the turbulence in the upper layer of a deep sea. The obtained calculated data on the coefficient of turbulent viscosity are compared with other indirect methods of determining the magnitudes of this coefficient in the sea. The results are summarised in the graphs, Figs.3-5, and for comparison the magnitudes of the coefficients of turbulent viscosity and of the amplitude of its changes obtained by Sverdrup and other authors are given in Table 2, p.1127. The results Card 1/2 given in the first part of the paper will enable quantitative

TITLE: The sea surface roughness parameter and the calculation of the turbulent momentum flux in the atmospheric layer adjacent to water

SOURCE: AN SSSR. Izvestiya. Fizika atmosfery i okeana, v. 1, no. 9, 1965, 973-988

TOPIC TAGS: atmospheric turbulence, sea water, surface water, lower atmosphere

ABSTRACT: The profiles of the average velocity in turbulent flows above a uniform stationary wall (in absence of significant temperature stratification) are described by a logarithmic formula. When this logarithmic boundary layer model is applied to the analysis of turbulent exchange processes above sea surfaces the problem arises concerning the determination and physical interpretation of the roughness parameter of a wavy water surface. The present article analyzes the drag of sea surfaces. The processing of a large amount of experimental data shows that 1) the roughness parameter z_0 depends not only on the absolute values of the spectral density of wind-induced waves but also on their frequency composition; 2) z_0 depends in the general case on the dynamical velocity v_d (friction speed), the wave height, phase velocity, and, possibly, on the mean square deviation of the free surface; 3) in spite of earlier attempts by various authors, the $z_0(v_d)$ relationship cannot be written down in a unique way, and a more promising approach seems to be the one considering z_0 a random function of

Cord 1/2

10
v₀; and 4) any average dependence of z₀ on v₀ should be introduced only after establishing the intervals of z₀ values for certain given probabilities; curves established by the authors show that the existing experimental material permits the correlation of any v₀ value with z₀ (varying by no more than one order of magnitude) with only 50% of probability.
